CHAPTER 1

Preliminaries

1. Clifford Algebras

Definition 1.1. Let V be a real finite dimensional vector space with a nondegenerate symmetric bilinear form $b : V \times V \to \mathbb{R}$. Then the **Clifford Algebra** of V is the data of a unital associative $\mathbb{R}$-algebra $\mathrm{Cliff}(V, b)$ and a linear map $i : V \to \mathrm{Cliff}(V, b)$ satisfying the following universal property: Given any linear map $\varphi : V \to A$ of V into any unital associative $\mathbb{R}$-algebra A satisfying $\varphi(v)^2 = b(v, v)$, there exists a unique map $\tilde{\varphi} : \mathrm{Cliff}(V, b) \to A$ such that the following diagram commutes:

$$
\begin{array}{ccc}
& V & \\
{\scriptstyle i} \downarrow & \searrow {\scriptstyle \varphi} & \\
\mathrm{Cliff}(V, b) & \xrightarrow{\tilde{\varphi}} & A
\end{array}
$$

Explicitly, we can construct $\mathrm{Cliff}(V, b)$ as a quotient of the tensor algebra

$$
\mathcal{T}(V) = \bigoplus_{n \in \mathbb{Z}^{\geq 0}} V^{\otimes n}
$$

by the left ideal generated by the elements $v \otimes v - b(v, v)$, and the map $i : V \to \mathcal{T}(V)/(v \otimes v - b(v, v))$ is given by the inclusion $V \hookrightarrow \mathcal{T}(V)$ followed by the quotient map. From this definition, it follows that the map i is injective, and we can identify V with it's image $i(V)$ as a subspace of $\mathrm{Cliff}(V, b)$. Using this identification, we can use the polarization identity to derive the useful relation

$$
vw + wv = 2b(v, w)
$$

In particular, if $b(v, w) = 0$, this implies that $vw = -wv$.

After fixing a basis for V, the bilinear form b will be given by a symmetric invertible matrix B, which is conjugate to a diagonal matrix where all the diagonal entries are either 1 or -1. If B has p positive entries and q negative entries, we say b has signature (p, q). Given a bilinear form b with signature (p, q), we then see that V admits a basis $\{e_i\}$ satisfying

(1) For $1 \leq i \leq p$, we have $b(e_i, e_i) = 1$
(2) For $p + 1 \leq j \leq p + q$, we have $b(e_j, e_j) = -1$
(3) For $i \neq j$, we have $b(e_i, e_j) = 0$

Any such basis then determines an isomorphism $(V, b) \to \mathbb{R}^{p|q}$, where $\mathbb{R}^{p|q}$ denotes $\mathbb{R}^{p+q}$ with the bilinear form with p 1's on the diagonal and q -1's. In addition, we get a basis for $\mathrm{Cliff}(V, b)$, given by

$$
\left\{ e_{i_1} e_{i_2} \cdots e_{i_k} \ : \ 0 \leq k \leq n, \ 1 \leq i_j \leq n \right\}
$$

where we interpret the product of 0 basis vectors to be the unit element 1. which then implies the dimension of $\mathrm{Cliff}(V, b)$ as a vector space is $2^{\dim V}$. This basis also determines an isomorphism $\mathrm{Cliff}(V, b) \to \mathrm{Cliff}_{p,q}(\mathbb{R})$, where $\mathrm{Cliff}_{p,q}(\mathbb{R})$ is the Clifford algebra for $\mathbb{R}^{p|q}$. Finally, this basis allows us to see that $\mathrm{Cliff}(V, b)$ has a $\mathbb{Z}/2\mathbb{Z}$ grading

$$
\mathrm{Cliff}(V, b) = \mathrm{Cliff}^0(V, b) \oplus \mathrm{Cliff}^1(V, b)
$$

Where $\mathrm{Cliff}^0(V, b)$ is the $\mathbb{R}$-span of all even products of basis vectors, and $\mathrm{Cliff}^1(V, b)$ is the $\mathbb{R}$-span of all odd products of basis vectors. In particular, $\mathrm{Cliff}^0(V, b)$ forms a subalgebra, and is called the **even subalgebra**, and we say that the elements of $\mathrm{Cliff}^0(V, b)$ are even. We then call $\mathrm{Cliff}^1(V, b)$ the odd subspace, and say

that its elements are odd. Elements that are contained in the odd or even subspace are called **homogeneous**, and given a homogeneous element $a \in \mathrm{Cliff}(V, b)$, we define it's **parity** $|a|$ as

$$|a| = \begin{cases} 0 & a \in \mathrm{Cliff}^0(V, b) \\ 1 & a \in \mathrm{Cliff}^1(V, b) \end{cases}$$

There is an extremely nice relationship between a Clifford algebra and it's even subalgebra.

THEOREM 1.2. *The even subalgebra* $\mathrm{Cliff}^0_{p,q}(\mathbb{R})$ *is isomorphic to both* $\mathrm{Cliff}_{p-1,q}$ *and* $\mathrm{Cliff}_{p,q-1}$ *as ungraded algebras (as long as $p - 1 > 0$ and $q - 1 > 0$.)*

PROOF. Fix a basis $\left\{ e_1^+, \ldots e_p^+, e_1^- \ldots e_q^- \right\}$ for $\mathbb{R}^{p|q}$, where $(e_i^+)^2 = 1$ and $(e_i^-)^2 = -1$. Then a quick computation shows that

$$(e_i^+ e_j^+)^2 = -(e_i^+)^2(e_j^+)^2 = -1$$
$$(e_i^- e_j^-)^2 = -(e_i^-)^2(e_j^-)^2 = -1$$
$$(e_i^+ e_j^-)^2 = -(e_i^+)^2(e_j^-)^2 = 1$$
$$(e_i^- e_j^+)^2 = -(e_i^-)^2(e_j^+)^2 = 1$$

Assume $q \neq 0$. Then a generating set for $\mathrm{Cliff}^0_{p,q}(\mathbb{R})$ is

$$\left\{ e_1^- e_j^+ \;:\; 1 \leq j \leq p \right\} \cup \left\{ e_1^- e_k^- \;:\; 2 \leq k \leq q \right\}$$

All the elements in the first set square to 1, and all the elements in the second set square to -1. We then get an isomorphism $\mathrm{Cliff}^0_{p,q}(\mathbb{R}) \to \mathrm{Cliff}_{p,q-1}$ via the mappings

$$e_1^- e_j^+ \mapsto e_j^+$$
$$e_1^- e_k^- \mapsto e_{k-1}^-$$

In the case $p \neq 0$, we can give a similar isomorphism, with all the plus signs swapped with the minus signs. ∎

Given two $\mathbb{R}$-algebras A and B, we can form their tensor product $A \otimes B$, which has $A \otimes B$ as the underlying vector space, and the multiplication is defined as

$$(a \otimes b)(c \otimes d) = ac \otimes bd$$

In the case that both A and B are $\mathbb{Z}/2\mathbb{Z}$ graded algebras, we have an alternate version of the tensor product, where the underlying vector space is also $A \otimes B$, but the multiplication is given by

$$(a \otimes b)(c \otimes d) = (-1)^{|b||c|}(ac \otimes bd)$$

We see that in the multiplication, we are formally commuting the elements of b and c, and we want to introduce a sign whenever elements are moved past each other. This is the **Koszul sign rule**.

2. The Classification of Clifford Algebras

One remarkable fact is that Clifford algebras are closed under the graded tensor product. For the remainder of this section, we will let $\otimes$ denote the graded tensor product.

THEOREM 2.1. $\mathrm{Cliff}_{p+t,q+s}(\mathbb{R}) \cong \mathrm{Cliff}_{p,q}(\mathbb{R}) \otimes \mathrm{Cliff}_{t,s}(\mathbb{R})$

PROOF. To give a map $\varphi : \mathrm{Cliff}_{p+t,q+s}(\mathbb{R}) \to \mathrm{Cliff}_{p,q}(\mathbb{R}) \otimes \mathrm{Cliff}_{t,s}(\mathbb{R})$, it is sufficient to specify it's action on $\mathbb{R}^{p+t|q+s}$, and checking that the Clifford relations hold. Let $\left\{ b_1^+, \ldots, b_{p+t}^+, b_1^-, \ldots b_{q+s}^- \right\}$ denote the standard orthogonal basis for $\mathbb{R}^{p+t|q+s}$ where $(b_i^+)^2 = 1$ and $(b_i^-)^2 = -1$. We then define the bases $\{ e_i^\pm \}$ and

$\{f_i^{\pm}\}$ analogously for $\mathbb{R}^{p|q}$ and $\mathbb{R}^{t|s}$ respectively. Then define φ by

$$\varphi(b_i^+) = \begin{cases} e_i^+ \otimes 1 & 1 \le i \le p \\ 1 \otimes f_i^+ & p+1 \le i \le p+t \end{cases}$$

$$\varphi(b_i^-) = \begin{cases} e_i^- \otimes 1 & 1 \le i \le q \\ 1 \otimes f_i^- & q+1 \le i \le q+s \end{cases}$$

This map is injective on generators, so if we show that this satisfies the Clifford relations, then the map given by extending the map to all of $\text{Cliff}_{p+t,q+s}(\mathbb{R})$ will be an isomorphism by dimension reasons. Showing the Clifford relations amounts to showing

(1) $\varphi(b_i^+)^2 = 1$
(2) $\varphi(b_i^-)^2 = -1$
(3) The images of any pair of distinct basis vectors anticommute.

The first two are relations are clear from how we defined φ. To show that the images of distinct basis vectors anticommute, there are serveral cases to consider. Given b_i^+ and b_j^+ where $1 \le i, j \le p$, they anticommute, because e_i^+ and e_j^+ anticommute. In the case where $1 \le i \le p$ and $p+1 \le j \le p+t$, we compute

$$\varphi(b_i^+)\varphi(b_j^+) + \varphi(b_j^+)\varphi(b_i+) = (e_i^+ \otimes 1)(1 \otimes f_j^+) + (1 \otimes f_j^+)(e_i^+ \otimes 1)$$
$$= e_i^+ \otimes f_j^+ - e_i^+ \otimes f_j^+$$

where we use the Koszul sign rule for the second term, noting that f_j+ and e_i^+ are both odd. The proof that the images of the b_i^- anti commute with each other, as well as the proof that the images of the b_i^+ and b_i^- anticommute are exactly the same. ∎

Because of this theorem, once we compute a few of the lower dimensional Clifford algebras, we will have enough data to fully classify all Clifford algebras over $\mathbb{R}$. In the case $p = q = 0$, we let $\text{Cliff}_{0,0}(\mathbb{R}) = \mathbb{R}$.

EXAMPLE 2.2 (*Some low dimensional examples*).

(1) As ungraded algebras, the Clifford algebra $\text{Cliff}_{0,1}(\mathbb{R})$ is isomorphic to $\mathbb{C}$, where the isomorphism is given by $e_1 \mapsto i$.
(2) As ungraded algebras, $\text{Cliff}_{0,2}(\mathbb{R})$ is isomorphic to the quaternions $\mathbb{H}$, where the isomorphism is given by $e_1 \mapsto i$ and $e_2 \mapsto j$.
(3) As a graded algebra, $\text{Cliff}_{1,1}(\mathbb{R})$ is isomorphic to $\text{End}(\mathbb{R}^{1|1})$. The isomorphism is given by

$$e_1^+ \mapsto \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} \qquad e_1^- \mapsto \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}$$

(4) As ungraded algebras $\text{Cliff}_{1,0}(\mathbb{R})$ is isomorphic to the product algebra $\mathbb{R} \times \mathbb{R}$, where $e_1 \mapsto (1, -1)$.
(5) As ungraded algebras, $\text{Cliff}_{2,0}(\mathbb{R})$ is isomorphic to $M_2\mathbb{R}$. The isomorphism is given by

$$e_1 \mapsto \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} \qquad e_2 \mapsto \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}$$

To classify all Clifford algebras as ungraded algebras, it suffices to know the following table:

$M_8\mathbb{C}$	$M_8\mathbb{H}$	$M_8\mathbb{H} \times M_8\mathbb{H}$	$M_{16}\mathbb{H}$	$M_{32}\mathbb{C}$	$M_{64}\mathbb{R}$	$M_{64}\mathbb{R} \times M_{64}\mathbb{R}$	$M_{128}\mathbb{R}$
$M_4\mathbb{H}$	$M_4\mathbb{H} \times M_4\mathbb{H}$	$M_8\mathbb{H}$	$M_{16}\mathbb{C}$	$M_{32}\mathbb{R}$	$M_{32}\mathbb{R} \times M_{32}\mathbb{R}$	$M_{64}\mathbb{R}$	$M_{64}\mathbb{C}$
$M_2\mathbb{H} \times M_2\mathbb{H}$	$M_4\mathbb{H}$	$M_8\mathbb{C}$	$M_{16}\mathbb{R}$	$M_{16}\mathbb{R} \times M_{16}\mathbb{R}$	$M_{32}\mathbb{R}$	$M_{32}\mathbb{C}$	$M_{32}H$
$M_2\mathbb{H}$	$M_4\mathbb{C}$	$M_8\mathbb{R}$	$M_8\mathbb{R} \times M_8\mathbb{R}$	$M_{16}\mathbb{R}$	$M_{16}\mathbb{C}$	$M_{16}\mathbb{H}$	$M_{16}\mathbb{H} \times M_{16}\mathbb{H}$
$M_2\mathbb{C}$	$M_4\mathbb{R}$	$M_4\mathbb{R} \times M_4\mathbb{R}$	$M_8\mathbb{R}$	$M_8\mathbb{C}$	$M_8\mathbb{H}$	$M_8\mathbb{H} \times M_8\mathbb{H}$	$M_{16}\mathbb{H}$
$M_2\mathbb{R}$	$M_2\mathbb{R} \times M_2\mathbb{R}$	$M_4\mathbb{R}$	$M_4\mathbb{C}$	$M_4\mathbb{H}$	$M_4\mathbb{H} \times M_4\mathbb{H}$	$M_8\mathbb{H}$	$M_{16}\mathbb{C}$
$\mathbb{R} \times \mathbb{R}$	$M_2\mathbb{R}$	$M_2\mathbb{C}$	$M_2\mathbb{H}$	$M_2\mathbb{H} \times M_2\mathbb{H}$	$M_4\mathbb{H}$	$M_8\mathbb{C}$	$M_{16}\mathbb{R}$
$\mathbb{R}$	$\mathbb{C}$	$\mathbb{H}$	$\mathbb{H} \times \mathbb{H}$	$M_2\mathbb{H}$	$M_4\mathbb{C}$	$M_8\mathbb{R}$	$M_8\mathbb{R} \times M_8\mathbb{R}$

To read the table, the bottom right entry is $\text{Cliff}_{0,0} \cong \mathbb{R}$, and moving to the right increments the signature from (p, q) to $(p, q+1)$, and moving up increments the signature (p, q) to $(p+1, q)$. Any other Clifford algebra can be obtained from an algebra on this table by tensoring with $M_{16}\mathbb{R}$, since incremeting the signature by 8 (by adding to either p or q) results in tensoring with $M_{16}\mathbb{R}$.

3. Clifford Modules

DEFINITION 3.1. A (left) ***Clifford module*** for the Clifford algebra $\text{Cliff}_{p,q}(\mathbb{R})$ is a module for $\text{Cliff}_{p,q}(\mathbb{R})$ in the usual sense i.e. a real vector space V equipped with an algebra action $\bullet : \text{Cliff}_{p,q} \times V \to V$ satisfying

  (1) Every element of $\text{Cliff}_{p,q}(\mathbb{R})$ acts linearly on V.
  (2) $(AB) \cdot v = A \cdot (B \cdot v)$ for all $v \in V$.
  (3) $(A + B) \cdot v = A \cdot v + B \cdot V$ for all $v \in V$.

Equivalently, it is the data of a real vector space V and a homomorphism $\text{Cliff}_{p,q}(\mathbb{R}) \to \text{End}(V)$.

DEFINITION 3.2. A Clifford module is ***irreducible*** if there exist no proper nontrivial submodules.

From the classification of Clifford algebras, all the Clifford algebras are either matrix algebras $M_n \mathbb{F}$, where $\mathbb{F} = \mathbb{R}, \mathbb{C}$, or $\mathbb{H}$, or products $M_n \mathbb{F} \times M_n \mathbb{F}$ of two copies of the same matrix algebra. This is sufficient to conclude that Clifford algebras are semisimple, so all Clifford modules will be direct sums of irreducible modules. Therefore, classifying all Clifford modules reduces to classifying the irreducible Clifford modules.

THEOREM 3.3. *Let $\mathbb{F} = \mathbb{R}, \mathbb{C}$, or $\mathbb{H}$. Then any nontrivial irreducible module for $M_n \mathbb{F}$ is isomorphic to $\mathbb{F}^n$ with the standard action.*

PROOF. We first note that $M_n \mathbb{F}$ acts transitively on $\mathbb{F}^n$, which implies that it is irreducible. We then must show that $\mathbb{F}^n$ is, up to isomorphism, the only irreducible $M_n \mathbb{F}$ module. The matrix algebra $M_n \mathbb{F}$ admits an increasing chain of left ideals

$$0 = I_0 \subset I_1 \subset \ldots \subset I_n = M_n \mathbb{F}$$

where I_k is the set of matrices where only the first k columns are nonzero. These ideals have the property that the quotient I_k / I_{k-1} is isomorphic to $\mathbb{F}^n$ as a left $M_n \mathbb{F}$ module. Then let M be some nontrivial irreducible $M_n \mathbb{F}$ module, and fix $m \in M$. Then the orbit $M_n \mathbb{F} \cdot m$ of m under the algebra action is a nonzero submodule, so it must be all of M. Then the map $\varphi : M_n \mathbb{F} \to M$ given by $A \mapsto A \cdot m$ is a surjective map of left $M_n \mathbb{F}$ modules. Then there must exist some smallest k such that $\varphi(I_k)$ is nonzero, and by construction, $\varphi|_{I_k}$ factors through the quotient I_k / I_{k-1}, which is isomorphic to $\mathbb{F}^n$ with the standard action. Then since $\mathbb{F}^n$ is irreducible, this gives us a nontrivial map between irreducible modules, which is an isomorphism by Shur's Lemma. ∎

THEOREM 3.4. *Any nontrivial irreducible module for $M_n \mathbb{F} \times M_n \mathbb{F}$ is isomorphic to either $\mathbb{F}^n$ where the left factor acts in the usual way, and the right factor acts by 0, or $\mathbb{F}^n$ where the left factor acts by 0 and the right factor acts in the usual way.*

PROOF. Let R denote $\mathbb{F}^n$ where the right factor acts nontrivially, and let L denote $\mathbb{F}^n$ where the left factor acts nontrivially. Both L and R are irreducible since $M_n \mathbb{F} \times M_n \mathbb{F}$ acts transitively on them. To show that they are the only irreducible modules up to isomorphism, we use a similar techinique as above. Let I_k denote the chain of increasing ideals in $M_n \mathbb{F}$, as we used above. Then $M_n \mathbb{F} \times M_n \mathbb{F}$ admits a chain of increasing left ideals J_k

$$0 = J_0 \subset I_1 \times \{0\} \subset \ldots \subset M_n \mathbb{F} \times \{0\} \subset M_n \mathbb{F} \times I_1 \subset \ldots \subset M_n \mathbb{F} \times M_n \mathbb{F} = J_{2n}$$

We note that for $1 \leq k \leq n$, we have that J_k / J_{k-1} is isomorphic to L, and for $n + 1 \leq k \leq 2n$, we have that J_k / J_{k-1} is isomorphic to R. Then given a nontrivial irreducible module M and a nonzero element m, we get a surjective map $\varphi : M_n \mathbb{F} \times M_n \mathbb{F}$ where $A \mapsto A \cdot m$. Like before, there exists some smallest k such that $\varphi(J_k)$ is nonzero, which then factors through to an isomorphism $J_k / J_{k-1} \to M$, so M is either isomorphic to R or L. ∎
